Bugs and debugging

The Very First Obstacle of Programming

- Syntax Error
  - A syntax error is an error in the source code of a program. Since computer programs **must follow strict syntax** to compile correctly, any aspects of the code that do not conform to the syntax of the programming language will produce a syntax error.

```
>>> x = 10
SyntaxError: invalid syntax
>>>
```

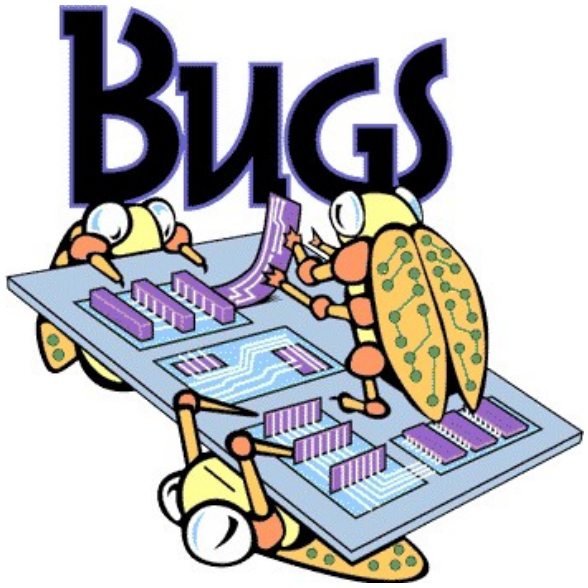
Sometime Errors are Fatal

- https://www.youtube.com/watch?v=VjJgiDuHlRw

Bugs?

- In 1947, Grace Murray Hopper was working on the Harvard University Mark II Aiken Relay Calculator (a primitive computer).

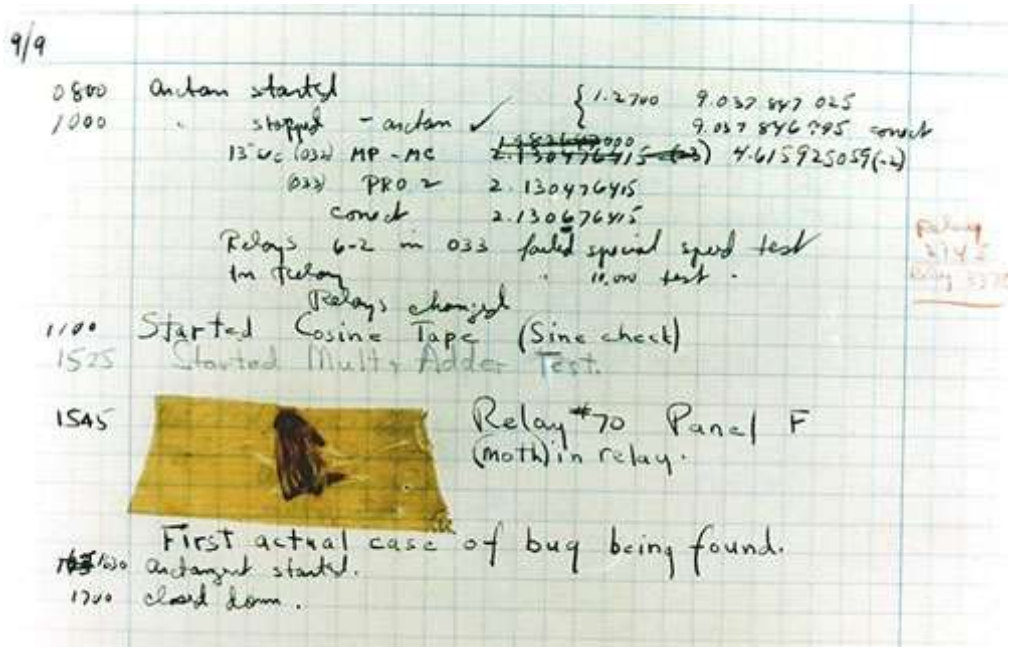
- On the 9th of September, 1947, when the machine was experiencing problems, an investigation showed that there was a moth trapped between the points of Relay #70, in Panel F.



Mark I

Bugs?

- The operators removed the moth and affixed it to the log. (See the picture above.) The entry reads: "First actual case of bug being found."



Humans make mistakes

You are only human

Therefore, you will make mistakes

Debugging

Debugging

- Means to remove errors (“bugs”) from a program.
- After debugging, the program is not necessarily error-free.
  - It just means that whatever errors remain are harder to find.
  - This is especially true for large applications.

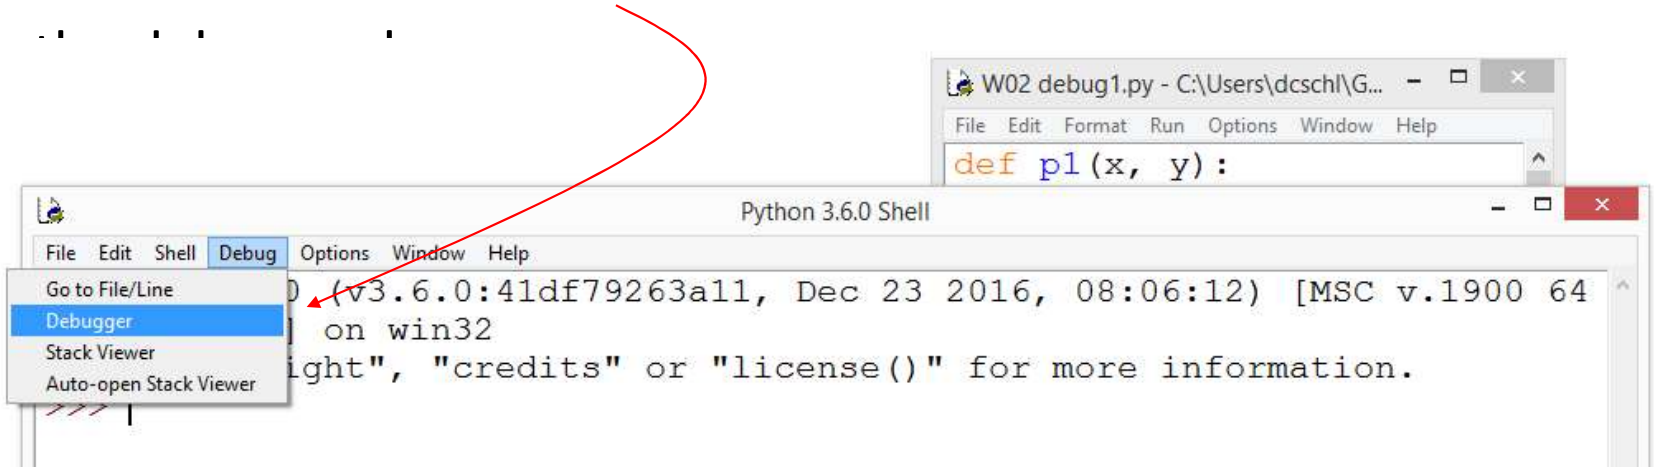
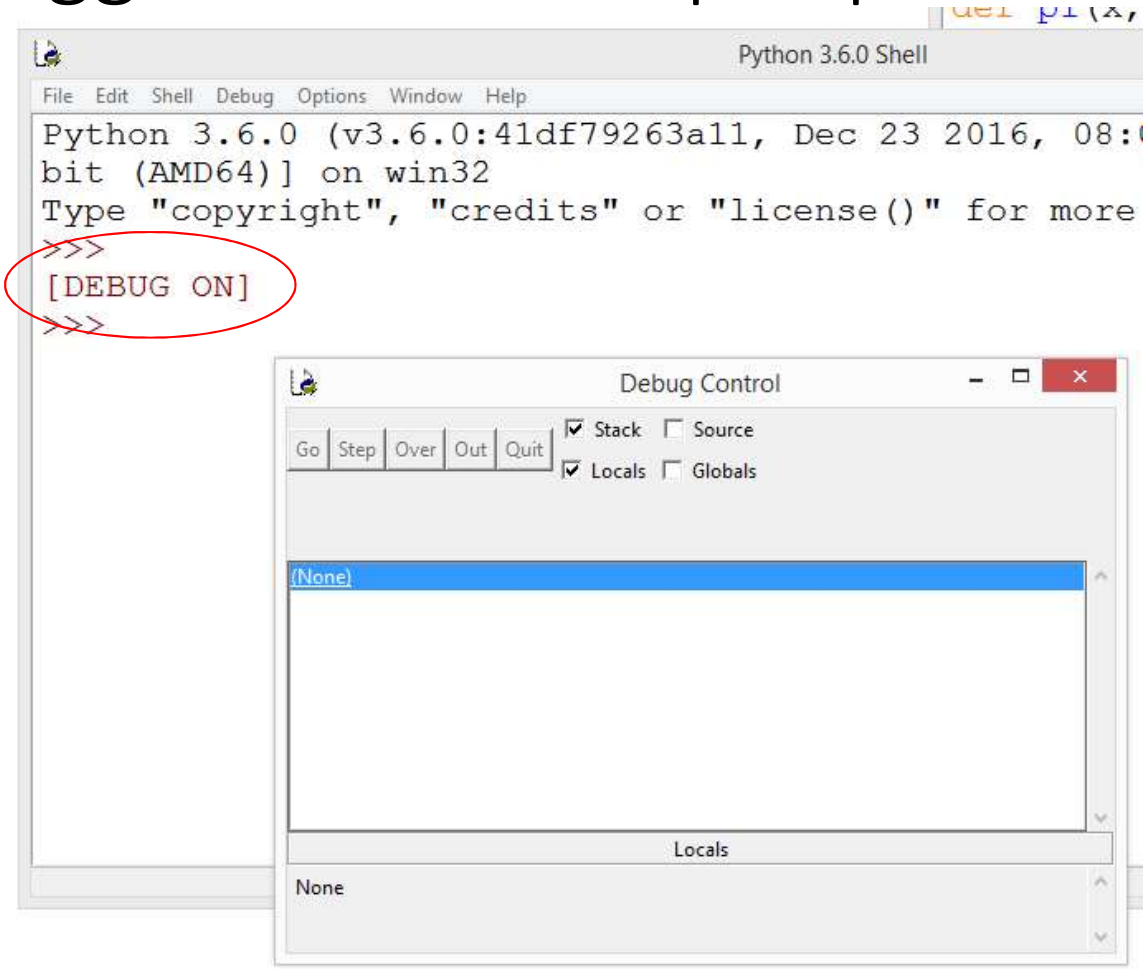
The IDLE Debugger

Using the IDLE Debugger

- Load in your source code
- Turn o

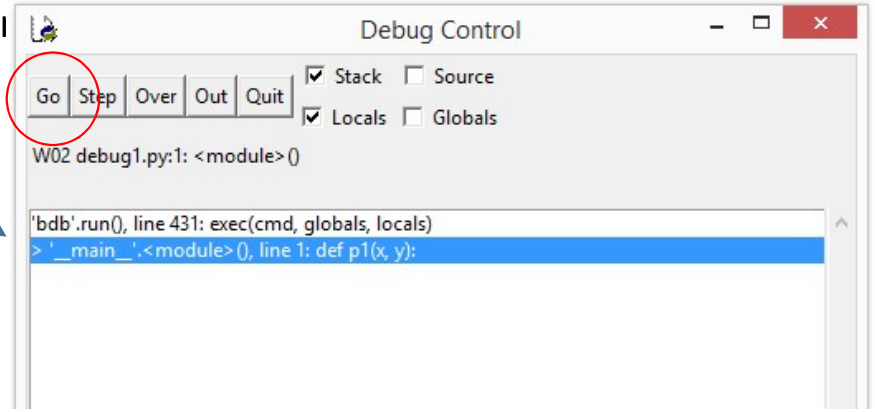


The Debugger Window Pops up



Using the IDLE Debugger

- Go to your source code window to “run”
- Then the debugger will pause the program at the first line of code and wait for you
- You can click the button “Go”
  - That will make the program run
  - At this point we don’t have any error
    - Because by “rui



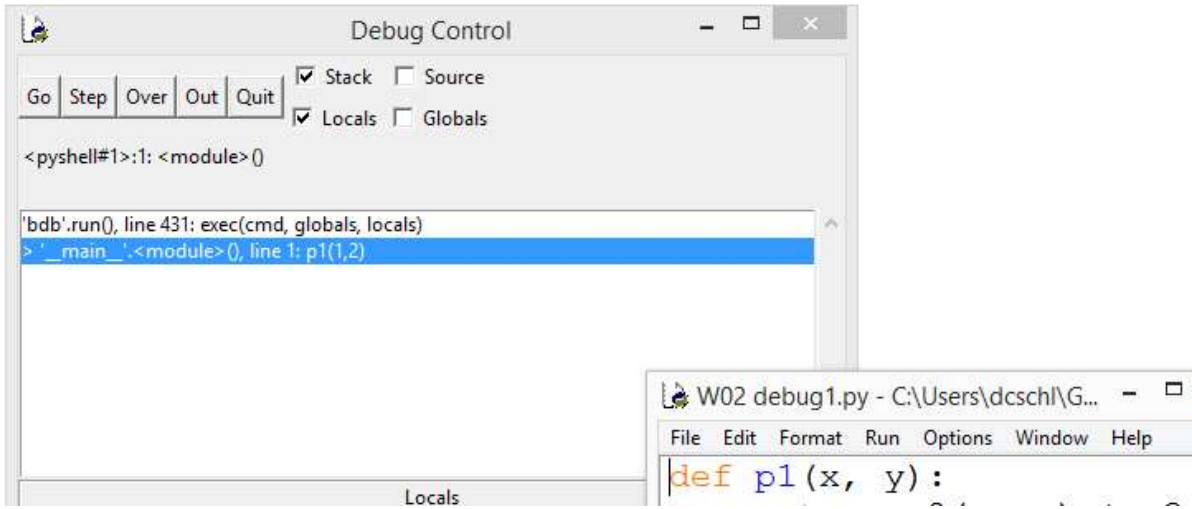
is

Using the IDLE Debugger

- Let's execute the function in debug mode
- In the shell, type

```
p1(1,2)
```

- Then the debugger will pause at the first line of p1
  - If you type "go" now, you will

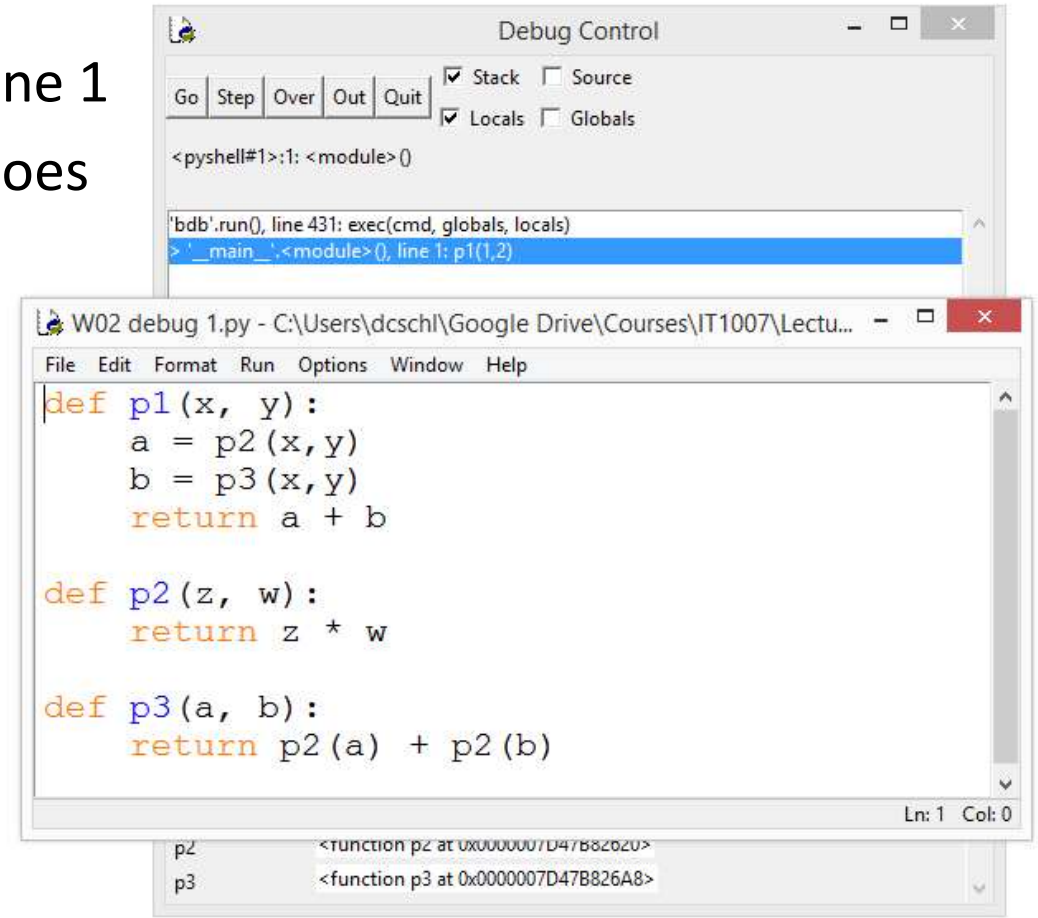


Using the IDLE Debugger

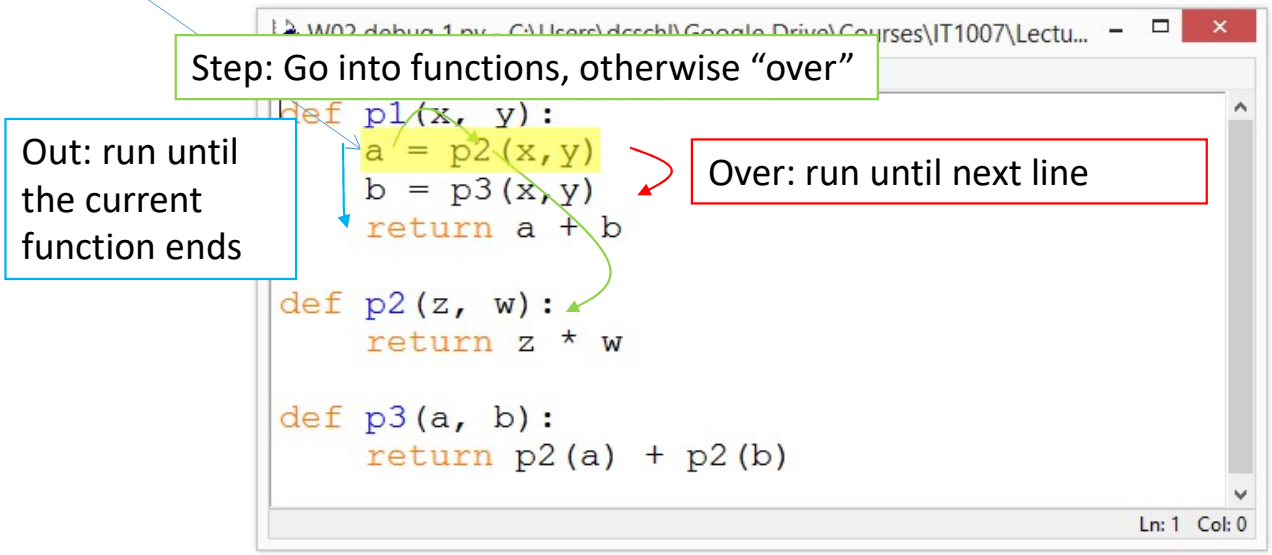
- Go
  - Clicking this will run the program until the next break point is reached. You can insert break points in your code by right clicking and selecting Set Breakpoint. Lines that have break points set on them will be highlighted in yellow.
- Step
  - This executes the next statement. If the statement is a function call, it will enter the function and stop at the first line.
- Over
  - This executes the next statement just as Step does. But it does not enter into functions. Instead, it finishes executing any function in the statement and stops at the next statement in the same scope.
- Out
  - This exits the current function and stops in the caller of the current function.
  - After using Step to step into a function, you can use Out to quickly execute all the statements in the function and get back out to the outer function.
- Quit: This terminates execution.

Using the IDLE Debugger

- Currently in line 1
- Click “Step” goes to line 2



Using the IDLE Debugger



More Debugging (BuggyAddNum)

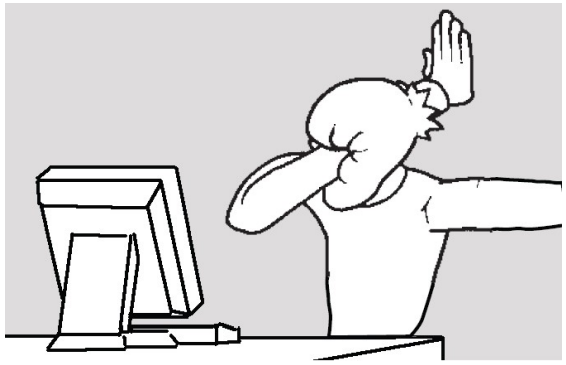
```
import random

def add2Num():
    number1 = random.randint(1, 10)
    number2 = random.randint(1, 10)

    print('What is ' + str(number1) + ' + ' + str(number2) + '?')
    answer = input()
    if answer == number1 + number2:
        print('Correct!')
    else:
        print('Nope! The answer is ' + str(number1 + number2))
```

```
>>> add2Num()
What is 4 + 9?
10
Nope! The answer is 13
>>>
```

```
>>> add2Num()
What is 6 + 5?
11
Nope! The answer is 11
>>> add2Num()
What is 5 + 9?
14
Nope! The answer is 14
>>>
```



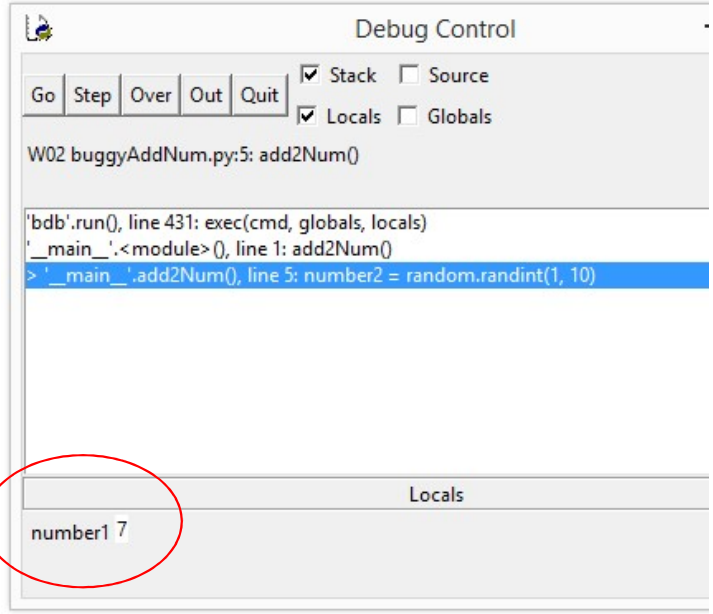
```
import random

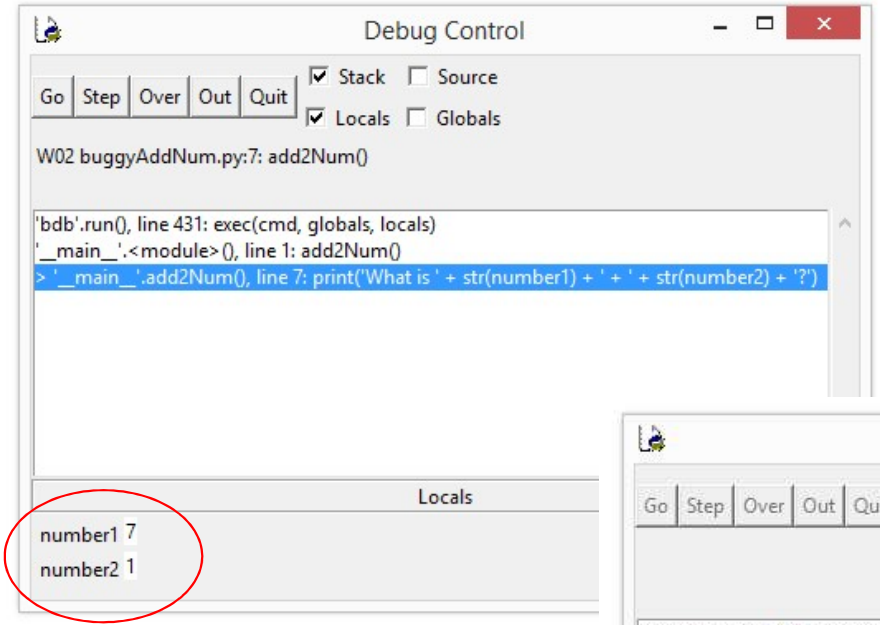
def add2Num():
    number1 = random.randint(1, 10)
    number2 = random.randint(1, 10)

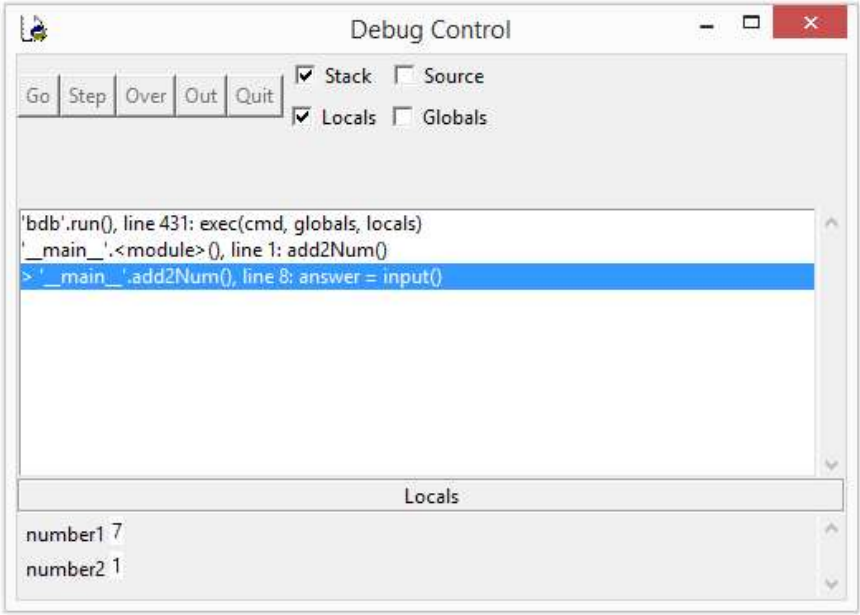
    print('What is ' + str(number1) + ' + ' + str(number2) + '?')
    answer = input()
    if answer == number1 + number2:
        print('Correct!')
    else:
        print('Nope! The answer is ' + str(number1 + number2))
```

Turn on Debugger

- After a few steps







```
>>> add2Num()
What is 7 + 1?
8
```

Using the IDLE Debugger

Start shared session

What are shared sessions?

Write code in Python 3.6

```
1  def p1(x, y):
2      a = p2(x,y)
3      b = p3(x,y)
4      return a + b
5
6  def p2(z, w):
7      return z * w
8
9  def p3(a, b):
10     return p2(a) + p2(b)
11
12 p1(1,2)
```

Support our research and practice Python by trying our new debugging skill test!

Start shared session

What are shared sessions?

Python 3.6

```
 1 def p1(x, y):
 2     a = p2(x,y)
 3     b = p3(x,y)
 4     return a + b
 5
 6 def p2(z, w):
 7     return z * w
 8
 9 def p3(a, b):
10     return p2(a) + p2(b)
11
12 p1(1,2)
```

Edit code | Live programming

line that has just executed

next line to execute

Click a line of code to set a breakpoint; use the Back and Forward buttons to jump there.

<< First | < Back | Program terminated | Forward > | Last >>

TypeError: p2() missing 1 required positional argument: 'w'

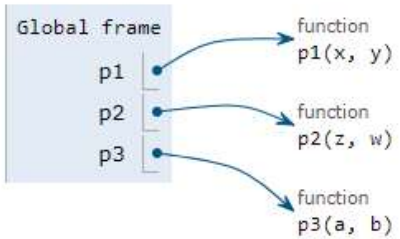
Frames Objects



Common Types of Errors

Common Types of Errors

- Omitting return statement

```
def square(x):
    x * x       # no error msg!
```

- Incompatible types

```
x = 5
def square(x):
    return x * x
x + square
```

- Incorrect # args

```
square(3,5)
```

Common Types of Errors

- Syntax

```
def proc(100)
    do_stuff()
        more()
```

- Arithmetic error

```
x = 3
y = 0
x/y
```

- Undeclared variables

```
x = 2
x + k
```

Common Types of Errors

- Infinite loop (from bad inputs)

```
def factorial(n):
  if n == 0:
    return 1
  else:
    return n * factorial(n-1)

fact(2.1)
fact(-1)
```

Common Types of Errors

- Infinite loop (forgot to decrement)

```
def fact_iter(n):
    counter, result = n, 1
    while counter!= 0:
        result *= counter
    return result
```

Common Types of Errors

- Numerical imprecision

```
def foo(n):
    counter, result = 0,0
    while counter != n:
        result += counter
        counter += 0.1
    return result

foo(5)
```

`counter` never exactly equals *n*

Common Types of Errors

- Logic

```
def fib(n):
  if n < 2:
    return n
  else:
    return fib(n-1) + fib(n-1)
```

How to debug?

- Think like a detective
  - Look at the clues: error messages, variable values.
  - Eliminate the impossible.
  - Run the program again with different inputs.
    - Does the same error occur again?

How to debug?

- Work backwards
  - From current sub-problem backwards in time
- Use a debugger
  - IDLE has a simple debugger
  - Overkill for our class
- Trace a function
- Display variable values

Displaying variables

```
debug_printing = True
def debug_print(msg):
  if debug_printing:
    print(msg)

def foo(n):
  counter, result = 0,0
  while(counter != n):
    debug_print(f'{counter}, {n}, {result}')
    counter, result = counter + 0.1, result + counter
  return result
```

Example

```
def fib(n):
  debug_print(f'n:{n}')
  if n < 2:
    return n
  else:
    return fib(n-1) + fib(n-1)
```

Other tips

- State assumptions clearly.

```
def factorial(n): # n integer >= 0
  if n == 0:
    return 1
  else:
    return n * factorial(n-1)
```

- Test each function before you proceed to the next.
  - Remember to test boundary cases

Summary

- Compound data helps us to reason at a higher conceptual level.
- Abstraction barriers separate usage of a compound data from its implementation.
- Only functions at the interface should be used.
- We can choose between different implementations as long as contract is fulfilled.

Debugging is an Art

Maths vs CS vs Engineering

- Three good friends, an engineer, a mathematician and a computer scientist, are driving on a highway that is in the middle of no where. Suddenly one of the tires went flat and they have no spare tire.

Maths vs CS vs Engineering

- Engineer
  - “Let’s use bubble gum to patch the tire and use the strew to inflate it again”
- Mathematician
  - “I can prove that there is a good tire exists in somewhere this continent”
- Computer Scientist
  - “Let’s remove the tire, put it back, and see if it can fix itself again”
